Corn for Silage
From the 2016 Environmental and Socioeconomic Indicators for Measuring Outcomes of On-Farm Agricultural Production in the United States

Field to Market: The Alliance for Sustainable Agriculture brings together a diverse group of grower organizations; agribusinesses; food, beverage, restaurant, and retail companies; conservation groups; universities; and public sector partners to create opportunities across the agricultural supply chain for continuous improvement in productivity, environmental quality, and human well-being. Field to Market offers America’s food and agriculture industries an essential tool for unlocking shared value for all stakeholders—a common framework for sustainability measurement that farmers and the supply chain can use to better understand and assess performance at the field, local, state, and national levels. The group provides collaborative leadership that is engaged in industry-wide dialogue, grounded in science and open to the full range of technology choices.

Field to Market is developing and piloting science and outcomes-based sustainability metrics, and tools at a variety of scales, to help measure and advance continuous improvement. The Field to Market 2016 Environmental and Socioeconomic Indicators Report analyzes sustainability trends over time at the national scale for six crops previously assessed: U.S. corn for grain, cotton, potatoes, rice, soybeans, and wheat, as well as four new crops: barley, corn for silage, peanuts, and sugar beets. Using publicly available data, the report evaluates performance over three decades.

Environmental Results
Over the study period (1980-2015), total production of corn for silage has increased slightly, while total planted area declined slightly from 1980 to 2015. The resource efficiency Indicators for Land Use, Energy Use, and Greenhouse Gas Emissions indicators have all improved steadily over the past 36 years; however, Energy Use and Greenhouse Gas Emissions have increased on a per-acre basis. Irrigation Water Use increased in the first 15 years of the study period, before beginning to decline (improve) after 2000.

The total change in 2015 when compared to 1980 for U.S. corn for silage production were as follows:

- **Production Trends**: Total corn for silage production increased (+24%) and total planted acres decreased (-23%) while crop yield increased (+58%).
- **Resource Efficiency**: Corn for silage improved resource efficiency with decreases in land use (-37%), energy use (-42%), and greenhouse gas emissions (-28%) per ton of silage; Soil conservation (tons of soil loss per acre) also improved. (-58%). There was an increase in irrigation water use (+10%) per ton of silage.
- **Per Acre and Total Resource Impact**: Corn for silage improved (decreased) energy use (-7%) and greenhouse gas emissions (-9%) per acre. Irrigation water per acre slightly increased (+4%). Total resource use increased for irrigation water use, but declined for energy use (-29%), greenhouse gas emissions (-12%), and total soil conservation improved, with a 72% decrease in total soil loss.

Figure 1. Index of resource use to produce corn for silage over time. Data are presented in index form, where the year 2000 = 1 and a 0.1-point change is equal to a 10 percent difference. Index values allow for comparison of change across multiple dimensions with differing units of measure. Year 2000 values are provided in the table.

Figure 2: Percentage change for corn for silage in each of the five primary indicators across four equal eight-year periods representing the full time series of this study. Percentage changes are calculated based on the difference between the two end-point years (e.g., percentage change in 2015 as compared to the value in 2007). See the full report for more details on the trends over time.
